

how to ideally set up a new uberspace instance

1. create uberspace
2. create SSH key (with password, key longer than RSA 8192)
3. integrate SSH key into kitty (or your preferred program)
4. login SSH
5. `uberspace tools version list php`
6. `uberspace tools version use php #(whatever is newest)`
7. do the same thing with any other software you have to use (like MongoDB and so on) now: set the newest version BEFORE you begin projects.
8. `uberspace web header set / Permissions-Policy "browsing-topics=()"`
(that's about Google Topics, formerly FLoC)
9. `uberspace web domain add (your domain)`
10. set DNS A records accordingly
